1. Introduction

The document at hands describes the ideas and the usage of the *SGAM-Toolbox* for developing Smart Grid systems in reference to the *Smart Grid Architecture Model (SGAM)* as introduced by the *Smart Grid Coordination Group (SGCG)* in 2012 [1].

It focuses on the SGAM-Toolbox and its' application and does not describe the underlying methods or technologies like Systems-Engineering, UML-based modeling or the handling of the involved modeling tool (*Enterprise Architect* from Sparx Systems¹).

If you have any feedback according the toolbox or need further help please feel free to contact us and send a mail to christian@en-trust.at.

Please take note of the available Video-Tutorials that demonstrate in detail how to utilize the SGAM Toolbox for architecting Smart Grid Systems. Simply follow the links on www.en-trust.at or search for "SGAM Toolbox" on YouTube.

¹ www.sparxsystems.com

2. The Smart Grid Architecture Model (SGAM)

The *Smart Grid Architecture Model (SGAM)* was introduced by the *Smart Grid Coordination Group* in 2012 [1].

The SGAM focuses on a structured description of a distributed Smart Grid System in order to identify standardization gaps. However, the proposed architecture model appears to be very useful for architecting smart grid systems. Hence, the SGAM Toolbox was developed in order to ease the modeling of Smart Grid Systems in reference to the SGAM.

The architecture model helps to analyze Smart Grid systems and interactions by mapping them to a three dimensional cube that is depicted in listing

Figure 1 - The Smart Grid Architecture Model (SGAM) [1]

The following subsections that comprise explanations for the single SGAM elements are taken from section “7.2 – SGAM Framework Elements” of the original, public available Smart Grid Coordination Group Document [1].

2.1. The Interoperability Layer

In order to allow a clear presentation and simple handling of the architecture model, the interoperability categories are aggregated into five abstract interoperability layers.

Business Layer: The business layer represents the business view on the information exchange related to smart grids. SGAM can be used to map regulatory and economic (market) structures and policies, business models, business portfolios (products & services) of market parties involved. Also business capabilities and business processes can be represented in this layer. In this way it supports business executives in decision making related to (new) business models and specific business projects (business case) as well as regulators in defining new market models.

Function Layer: The function layer describes functions and services including their relationships from an architectural viewpoint. The functions are represented independent from actors and physical implementations in applications, systems and components. The functions are derived by extracting the use case functionality which is independent from actors.

Information Layer: *The information layer describes the information that is being used and exchanged between functions, services and components. It contains information objects and the underlying canonical data models. These information objects and canonical data models represent the common semantics for functions and services in order to allow an interoperable information exchange via communication means.*

Communication Layer: *The emphasis of the communication layer is to describe protocols and mechanisms for the interoperable exchange of information between components in the context of the underlying use case, function or service and related information objects or data models.*

Component Layer: *The emphasis of the component layer is the physical distribution of all participating components in the smart grid context. This includes system actors, applications, power system equipment (typically located at process and field level), protection and tele-control devices, network infrastructure (wired / wireless communication connections, routers, switches, servers) and any kind of computers.*

2.2. The Smart Grid Plane

Every layer itself is depicted by the utilization of the Smart Grid Plane, which is defined as follows:

In general power system management distinguishes between electrical process and information management viewpoints. These viewpoints can be partitioned into the physical domains of the electrical energy conversion chain and the hierarchical zones (or levels) for the management of the electrical process (refer to [IEC62357-2011, IEC 62264-2003]). Applying this concept to the smart grid conceptual model introduced in section 6.3 allows the

foundation of the Smart Grid Plane (see Figure 7.). This smart grid plane enables the representation on which levels (hierarchical zones) of power system management interactions between domains take place.

According to this concept those domains, which are physically related to the electrical grid (Bulk Generation, Transmission, Distribution, DER, Customer Premises) are arranged according to the electrical energy conversion chain. The conceptual domains Operations and Market are part of the information management and represent specific hierarchical zones. The conceptual domain Service Provider represents a group of actors which has universal role in the context of smart grid. This means that a Service Provider can be located at any segment of the smart grid plane according to the role he has in a specific case.

2.3. Domains

The Smart Grid Plane covers the complete electrical energy conversion chain, as described in Table 1 - SGAM Domains.

Domain	Description
Bulk Generation	Representing generation of electrical energy in bulk quantities, such as by fossil, nuclear and hydro power plants, off-shore wind farms, large scale solar power plant (i.e. PV, CSP)– typically connected to the transmission system
Transmission	Representing the infrastructure and organization which transports electricity over long distances
Distribution	Representing the infrastructure and organization which distributes electricity to customers
DER	Representing distributed electrical resources directly connected to the public distribution grid, applying small-scale power generation technologies (typically in the range of 3 kW to 10.000 kW). These distributed electrical resources may be directly controlled by DSO
Customer Premises	Hosting both - end users of electricity, also producers of electricity. The premises include industrial, commercial and home facilities (e.g. chemical plants, airports, harbors, shopping centers, homes). Also generation in form of e.g. photovoltaic generation, electric vehicles storage, batteries, micro turbines... are hosted

Table 1 - SGAM Domains

2.4. Zones

The SGAM zones represent the hierarchical levels of power system management [IEC62357-2011]. These zones reflect a hierarchical model which considers the concept of aggregation and functional separation in power system management. The basic idea of this hierarchical model is laid down in the Purdue Reference Model for computer-integrated manufacturing which was adopted by IEC 62264-1 standard for —enterprise-control system integrationII [IEC 62264-2003]. This model was also applied to power system management. This is described in IEC 62357 —Reference architecture for object models servicesII [IEC 62357-2003, IEC 62357-1-2012].

The concept of aggregation considers multiple aspects in power system management:

- Data aggregation – data from the field zone is usually aggregated or concentrated in the station zone in order to reduce the amount of data to be communicated and processed in the operation zone

- Spatial aggregation – from distinct location to wider area (e.g. HV/MV power system equipment is usually arranged in bays, several bays form a substation; multiple DER form a plant station, DER meters in customer premises are aggregated by concentrators for a neighborhood)

In addition to aggregation the partitioning in zones follows the concept of functional separation. Different functions are assigned to specific zones. The reason for this assignment is typically the specific nature of functions, but also considering user philosophies. Real-time functions are typically in the field and station zone (metering, protection, phasor-measurement, automation...). Functions which cover an area, multiple substations or plants, city districts are usually located in operation zone (e.g. wide area monitoring, generation scheduling, load management, balancing, area power system supervision and control, meter data management...).

The SGAM zones are described in Table 2 - SGAM Zones

Zone	Description
Process	Including the physical, chemical or spatial transformations of energy (electricity, solar, heat, water, wind ...) and the physical equipment directly involved. (E.g. generators, transformers, circuit breakers, overhead lines, cables, electrical loads any kind of sensors and actuators which are part or directly connected to the process,...).
Field	Including equipment to protect, control and monitor the process of the power system, e.g. protection relays, bay controller, any kind of intelligent electronic devices which acquire and use process data from the power system.
Station	Representing the areal aggregation level for field level, e.g. for data concentration, functional aggregation, substation automation, local SCADA systems, plant supervision...
Operation	Hosting power system control operation in the respective domain, e.g. distribution management systems (DMS), energy management systems (EMS) in generation and transmission systems, microgrid management systems, virtual power plant management systems (aggregating several DER), electric vehicle (EV) fleet charging management systems.
Enterprise	Includes commercial and organizational processes, services and infrastructures for enterprises (utilities, service providers, energy traders ...), e.g. asset management, logistics, work force management, staff training, customer relation management, billing and procurement...
Market	Reflecting the market operations possible along the energy conversion chain, e.g. energy trading, mass market, retail market.

Table 2 - SGAM Zones

3. SGAM Toolbox Architecture

The SGAM Toolbox mainly consists of three components:

1. SGAM MDG Technology
2. SGAM Model Templates
3. SGAM Reference Data

The definition of the elements that can be used to model a SGAM related project is done by the use of MDG Technology. The SGAM MDG Technology holds these definitions.

To ease the work with the Toolbox some Model Templates have been created. They are based on the above mentioned definitions and can be accessed via the New Model Wizard.

The SGAM Reference Data holds some Information concerning the representation of defined elements and some definitions for a Model-Import or -Export.

Figure 2 - The SGAM Toolbox Architecture

The most important element of the SGAM Toolbox is the SGAM Metamodel, which is derived from the SGAM and delivers the available elements and their relations.

Figure 3 - The SGAM Metamodel depicts the SGAM Metamodel as rough overview without mentioning the individual attributes (implemented as Tagged Values).

Figure 3 - The SGAM Metamodel

4. SGAM Toolbox Installation

The Toolbox Installation Package describes the necessary steps on how to install the SGAM Toolbox. The Toolbox itself consists of a folder labeled "SGAM Toolbox". The folder's subfolders and elements are structured according to the Toolbox Architecture, which can be found in Figure 2 - The SGAM Toolbox Architecture.

Figure 4 - SGAM Toolbox Installation

Please Note: You are required to make use of some specific Enterprise-Architect functions here. It is not stated here, where to find these functions. This is due to the fact that it depends on your version of Enterprise Architect where to find the functions. Please use the very, very, very useful Enterprise Architect Help to learn more about these functions.

Element	Notes
Step 1 – Copy Project Templates	Copy the Project Templates to the local Model Pattern Directory. The Project Templates are xml-files. You can find them under "SGAM Toolbox\Model Templates" Copy them to your local Model Pattern Directory. This directory looks like "C:\Program Files\Sparx Systems\EA\ModelPatterns"
Step 2 – Import Reference Data	Import Reference Data Use the "Import Reference Data" Function from Enterprise Architect to import the SGAM Reference Data.

	<p>--> Learn about this function by using the "help" from Enterprise Architect.</p> <p>The SGAM Reference Data is a xml file that can be found under "SGAM Toolbox\Reference Data\SGAM Toolbox Reference Data.xml"</p> <p><u>Check if you succeeded:</u></p> <p>Open any diagram, navigate to "Swimlanes and Matrix" and select the "Matrix" Register Card.</p> <p>Among the "Model Profiles" in this Register Card you should find 5 SGAM Layer Profiles, labeled in the way "SGAM_Function_Layer".</p>
Step 3 – Import MDG Technology	<p><u>Use the MDG-Technology Import function to install the SGAM Toolbox.</u></p> <p>Typically you find it under "Tools → MDG Technology Import". Use the Enterprise Architect Help to learn more about this function.</p> <p>The file to import is an xml file named "SGAM Toolbox.xml". You can find it under "SGAM Toolbox\SGAM Toolbox.xml"</p> <p>You will have to restart Enterprise Architect after importing.</p>
Step 4 – Create a new SGAM Project	<p><u>Use the "New Model Wizard" to create your own SGAM Project</u></p> <p>Select "New Model from Pattern" in the Project Browser to launch the Model Wizard. Choose the SGAM-Toolbox in the "Technology" Section. On the right side you can select the SGAM Model you want to create.</p> <p>Hint 1: It is useful to work with a "Project Template Package" to make the elements automatically appear in a specified layout. E.G., use the rectangular Notation for Use Cases in the SGAM plane. The Toolbox delivers an initial Project Template Package that can be generated with the Model Wizard.</p> <p>Hint 2: You can find a complete example on www.en-trust.at which could serve as quite good starting point.</p>

6. Proposed Development Process

The proposed development process is inspired from the Use Case Mapping Process (UCMP) as introduced by [1].

It basically consists of three phases, where the first two phases reflect the main tasks of the UCMP, but in an adopted schedule.

First, during the System Analysis Phase, the systems functionality is to be described. This is done by executing a Use Case Analysis, developing the SGAM Function Layer and developing the SGAM Business Layer.

Next, during the System Architecture Phase, the development of the Component, the Information and the Communication Layer is done.

The Design & Development Phase, which addresses the realization of individual systems, is not SGAM specific and hence can be done by means of classic systems engineering methods. It is conceptualized as iterative phase to highlight the idea of suggested agile development.

The following sections describe the steps to be performed in more detail.

Please refer to the provided video tutorials to learn more about the application of this development process and the steps that have to be done during the execution of each task.

Figure 5 - SGAM Development Process

Element	Notes
System Analysis Phase	During the System Analysis Phase the specification for the system to be built has to be developed. Therefore it is necessary to identify the project-roles, the stakeholder and their individual requirements and the interrelation of the project with its environment and its project context.
Computation Independent Model (CIM)	The Term "Computation Independent Model" is taken from Model Driven Architecture (MDA). It focuses on the desired behaviour and function of a system without mentioning how the system is implemented (Separation of concerns).
System Architecture Phase	The System Architecture Phase is used to map the prior defined functionalities to a basic architecture. This basic architecture consists of the major function blocks and the concerning interfaces of the whole system.
Platform Independent Model (PIM)	The "Platform Independent Model" aims to identify major function blocks without relating them to a concrete implementation
Design & Implementation Phase	The Design & Implementation Phase is designed as iterative process. The underlying idea is to support agile development aspects. During this phase, a prior developed architecture is designed and implemented.
Platform Specific Model (PSM)	The "Platform Specific Model" describes the design for the specific components. The design is done with respect to the selected platform.
Platform Specific Implementation (PSI)	The "Platform Specific Implementation" is the last Layer of the MDA deliverables. As the name mentions, it depicts the implementation itself.

7. System Analysis Phase

7.1. Use Case Analysis

The execution of the Use Case Analysis is one of the key tasks that has to be performed. It focuses on the identification of involved actors and goals and on the decomposition of the Product-Owner inputs into single Use Cases. As the identified model elements state the basis for all further modeling, this is a very crucial task and should obtain the necessary attention.

Figure 6 - Use Case Analysis

The three tasks of the Use Case Analysis are described in the following subsections in detail.

7.1.1. Develop Business Case Model

Focus of this task is the identification of involved *Business Actors (BA)*, their assigned *Business Goals (BG)* and individual *Business Cases (BC)* that are performed by the BA in order to reach the individual BG. In addition, *High Level Use Cases (HLUC)* are identified and modeled that are included by the BC.

After creating a new Enterprise Architect project with an empty model you can make use of the *Model Wizard* to get a template for the development of the Business Case Model.

1. Start the Model Wizard (Menu → Project → New Model) and select "SGAM Toolbox" as Technology and "SGAM Business Layer" as model template. Of course you can also create the single packages and diagrams manually, but for the beginning the template is useful to get an idea about the concept.

This step creates a new package named "SGAM Business Layer" within your model. The content of this package is an example that illustrates, how a Business Case Model looks like.

Developing your own Business Case Model comprises the following steps:

2. Model the identified **Business Actors** by making use of the Model Element “Business Actor”. This element can be found in the View “Toolbox” and placed by drag and drop onto the diagram.
3. Model the individual **Business Goals** for every Business Actor by using the element “Business Goal”. Bring them into relation with the concerning Business Actor by making use of the “dependency” relation.
4. Model the **Business Cases** that are performed by the Business Actors in order reach the individual Business Goals. The relation between Business Actor and Business Case is of type “use”; the relation between Business Case and Business Goal is of type “realize”. Typically numerous Business Cases exist. You can make use of all UML Use Case relations to model the dependencies between them. It is also a good practice to make diagrams composit in order to reduce complexity.
5. Identify and model specific **High Level Use Cases** by making use of the element “High Level Use Case”. Bring them in relation with individual Business Cases by making use of the “invoke” relation. Say, a Business Case invokes High Level Use Cases.

Please note that every Business Case from the template is linked to an individual SGAM Business Layer Diagram. These diagrams will be modeled after finishing the SGAM Function Layer, as there will be defined which domains and zones are affected by each related High Level Use Case.

Figure 7 - Business Case Model (Example)

7.1.2. Develop High Level Use Case Model

After the identification of the involved High Level Use Cases (HLUC) in the prior executed task they need to be described in more detail. The description of the HLUCs consists of two basic steps. First, model the relations between the individual HLUC's by making use of the standard Use Case relationships from the UML. Next, decompose every single HLUC in more granular Primary Use Cases (PUC) and describe their cooperation. These modeling tasks are performed at the level of the SGAM Function Layer. For the ease of use, the SGAM Toolbox provides some adequate templates which can be used for modeling as described below:

1. *Start the Model Wizard (Menu → Project → New Model) and select “SGAM Toolbox” as Technology and “SGAM Function Layer” as model template. Of course you can also create the single packages and diagrams manually, but for the beginning the template is useful to get an idea about the concept.*

This step creates a new package named “SGAM Function Layer” within your model. The content of this package is an example that illustrates, how a model of HLUCs and PUCs could look like. Besides the model itself the package shows the best practice for structuring your model: Inside the package is a SGAM Function Layer diagram located that is used to depict the relations between the single HLUCs. For every HLUC an individual Sub-Package with the name of the corresponding HLUC and the stereotype “*HLUC*” is integrated. Each of these Sub-Packages holds two diagrams of type SGAM Function Layer. The first diagram is used to decompose the HLUC into more granular PUCs and to describe their relations. The second diagram is used to locate the involved PUCs within the SGAM plane, consisting of domains and zones. Again, for every PUC an individual Sub-Package with the name of the PUC and the stereotype “*PUC*” exists.

To create your own High Level Use Case Model follow the steps below:

2. *Place all HLUC's you identified during the prior task on the Top-Level Diagram in the SGAM Function Layer Package and model the relations between them.*
3. *To keep your model clean and to enhance the readability of the later on generated reports, create a package structure as described above and move the HLUCs from the SGAM Business Layer package to the corresponding Sub-Package in the SGAM Function Layer Package.*
4. *For every HLUC Sub-Package create a diagram of type “SGAM Function Layer”*
5. *Decompose the HLUC into more granular PUCs and describe their cooperation. It is good practice to make use of Activity Diagrams to do so. To create compact information you can also place the Activity Diagram itself on this diagram. Depict functional interrelations between single PUCs by making use of the “Functional Interrelation” relation.*
6. *Hint: You can automatically generate an Activity Diagram from the HLUC. To do so, you have to invoke the single PUCs within the “Scenario” description of the HLUC. Please learn more about “Scenarios” and “Generate Diagrams” in the Enterprise Architect Help.*

Control Electric Load from Thermal Energy System

Figure 8 - High Level Use Case Model (Example)

Name: Control Electric Load from Thermal Energy Generation
 Author: Christian Neuheller
 Version: 0.1.1
 Created: 21.11.2013 14:32:41
 Updated: 28.11.2013 23:39:35

7.1.3. Develop Primary Use Case Model

The aim of this task is a more detailed description for every single Primary Use Case (PUC) developed in the prior task. Basically it is valid to make use of any possibility that helps understanding the functionality of the PUC. In praxis it is useful to describe all PUCs in a similar way. A proven method is to describe the PUCs by using Activity and Sequence Diagrams. Enterprise Architect comprises a very powerful possibility for an automated generation of these diagrams. Creating the descriptions that way is a very efficient approach for modeling the PUCs. To make use of this possibility follow the steps below:

1. *Create a SGAM Function Layer Diagram within every PUC Sub-Package and place the corresponding PUC in it.*
2. *Describe the functionality of the PUC in any text editor (or use the available Product-Owner description). Write in a way, that every sentence represents one step or Activity of the PUC and write every sentence in a new line. Try to create sentences that hold the name of every involved actor and every exchanged information. For example instead of "Actor A sends Voltage Measurement to Actor B. Actor B responds with the new operation point" write "Actor A sends Voltage Measurement to Actor B. Actor B transmits Operation Point to Actor A.". Now, copy the written text to the clipboard.*
3. *Open the properties dialog of the corresponding PUC and select "Scenarios" from the "Rules" menu on the left. Here, select the "Structured Specification" tab and right click into the Action description field. Now you can select to "create structure from clipboard text". Doing this, creates for every sentence written before a single step in the Use Case description. After this, you can close the property.*
4. *Create for every Actor involved the corresponding Model Element (SGAM Actor) and link it to the PUC. Take care to name the actors the same way as they are called in the textual description. Of course, if the Actor already exists in your model, do not create it again but place and link the existing one. If you open the Scenario Description within the PUC properties dialog again, you will see that the name of the connected actor is now underlined.*
5. *Having all involved Actors linked to the PUC, you can generate an Activity and Sequence Diagram automatically. In the menu bar of the "Structured Specification" tab you can find the Icon for "Generate Diagrams". Here you can select which type of diagrams you want to generate.
Please Note: The described functionality is very powerful and enables you to describe Use Cases in a very efficient way. You can manipulate the activity diagram and update the structured description with the changes. Of course it is also possible to create alternate and exception paths and much more. Please refer to the very valuable Enterprise Architect Help to learn more about these capabilities.*
6. *In the generated Activity Diagram you can analyze the PUC and create model elements for every Information Item transmitted. Use the element "Information Object" for this task. As this diagram is of type "Activity Diagrams" you won't find this element in the toolbox. You have to select the SGAM Function Layer toolbox by clicking on "More tools..." at the top of the toolbox and selecting "SGAM-Toolbox / SGAM Function Layer". Depict the relation between a single Activity (Use Case Step) and the Information Item by means of the "dependency" relation.*
7. *In the generated Sequence Diagram you can attach the created Information Items to the corresponding sequence. Right click on the corresponding connection and select "Advanced/Information Flows Realized". In the appearing dialog click on "click to create new information flow...". A package browser opens where you can select the referred Information Item. Again, please refer to the Enterprise Architect Help to learn more.*
8. *You can place the generated Activity and Sequence Diagrams directly in the PUC diagram simply by using "drag and drop". This helps, as you have all relevant description – the PUC and it's involved actors, the algorithmic aspect (activity diagram) and the communication aspect (sequence diagram) – in one diagram that will be used during reporting.*

Figure 9 - Primary Use Case Model (Example)

7.2. Develop Function Layer

The SGAM Function Layer describes the location of all involved Primary Use Cases (PUC) and Actors for a specific High Level Use Case (HLUC). Hence, it has to be developed for every HLUC separately. The steps below describe how to create the SGAM Function Layer for a single HLUC.

1. Use the SGAM Function Layer Template to create a new SGAM Function Layer Diagram inside the "HLUC" package.
2. To make the SGAM Plane (domains and zones) visible, open "Diagram" in the pull down menu and select the "Swimlanes and Matrix" dialog. Within the register card "Matrix" you can select a Model Profile. Select the "SGAM Function Layer" Profile and activate the Check-Box "activate" at the top.
3. Place all involved PUCs and Actors in the diagram and arrange them in respect to the corresponding domains and zones.

Figure 10 - Develop Function Layer

Figure 11 - SGAM Function Layer (Example)

7.3. Develop Business Layer

The focus of the SGAM Business Layer is to show the affected domains and zones for every Business Case and hence has to be modeled for each of them. It is suggested to use the involved High Level Use Cases as model elements. The steps below describe how to model the SGAM Business Layer for a single Business Case.

1. Use the SGAM Business Layer template to create a new SGAM Business Layer diagram for every Business Case (New Diagram/SGAM Toolbox/SGAM Business Layer)
2. To make the SGAM Plane (domains and zones) visible, open "Diagram" in the pull down menu and select the "Swimlanes and Matrix" dialog. Within the register card "Matrix" you can select a Model Profile. Select the "SGAM Business Layer" Profile and activate the Check-Box "activate" at the top.
3. For every invoked HLUC open the SGAM Function Layer diagram and analyze which domains and zones are affected.
4. Go to the SGAM Business Layer diagram and place the corresponding HLUC in it. Switch the appearance of the HLUC to rectangular (right click / Advanced / Use Rectangular Notation)

5. Locate and resize the HLUC according to the affected domains and zones. Having done this for all HLUCs, you see which domains and zones are affected by the Business Case in total.
6. Place the Business Case in the diagram (at the bottom of the Z-Order), switch to rectangular notation and resize and locate it according to the totally affected domains and zones.

Figure 12 - Develop Business Layer

Figure 13 - SGAM Business Layer (Example)

8. System Architecture Phase

8.1. Develop Component Layer

The development of the SGAM Component Layer represents the model transformation from the Computational Independent Model (CIM) to the Platform Independent Model (PIM). This transformation maps the functional description of the system to a general, architectural solution.

Hence, in a first step a mapping from logical actors to physical components has to be done. Next, the identified physical actors are utilized to create the SGAM component layer. Both steps can be executed by usage of the supplied Component Layer Template.

Figure 14 - Develop Component Layer

8.1.1. Map Actors to physical Components

To perform the mapping of the logical Actors (as created in the Function Layer) to physical Components follow the steps below:

1. Use the SGAM Component Layer template to create a new SGAM Component Layer diagram
2. Place all involved logical Actors to the diagram
3. Create a physical representation (component) for every Actor. This physical representation can either be a specific component or a Software Application. You can use the appropriate model elements from the toolbox for this step. Use the “trace” relation to depict the model transformation step. You can also create new Components by using the general “Component” element. It is also possible to use your own images for these Components. Please use the Enterprise Architect Help to learn more about this possibility.
4. If a Software Application is introduced, you need to create a “Computer” Component as well. Use the “hosts” relation to show, which computer hosts which Software Application.

Figure 15 - Actor Mapping Model (Example)

8.1.2. Develop Component Layer

The development of the SGAM Component Layer can be done by following the steps below:

1. Use the SGAM Component Layer template to create a new SGAM Component Layer
2. To make the SGAM Plane (domains and zones) visible, open “Diagram” in the pull down menu and select the “Swimlanes and Matrix” dialog. Within the register card “Matrix” you can select a Model Profile. Select the “SGAM Component Layer” Profile and activate the Check-Box “activate” at the top.
3. Place all prior created physical components within the plane in the corresponding domain and zone.
4. Create additional necessary components, like ICT-Networks (represented as clouds), Electric Networks (e.g. “Medium Voltage Network”) or electric components like Transformers. Following the modeling-concepts you can of course make single components like for example ICT-Networks “composite” and describe them in more detail. Please refer to the Enterprise Architect Help to learn more about this possibility.
5. Model the relations between the individual components. You can use the “Electric Association” relation to depict electric connections, especially along the electric conversion chain in the process zone, and “ICT Association” to model ICT connections.

Figure 16 - SGAM Component Layer (Example)

8.2. Develop Information Layer

Focus of this task is to model the information object flows between the single components and to identify proper data model standards that are suitable to reflect these information objects.

The development of the Information Layer consists of three consecutive tasks as described in the following subsections.

You can make use of the Model Wizard to create the involved diagrams automatically:

1. Start the Model Wizard (Menu → Project → New Model) and select “SGAM Toolbox” as Technology and “SGAM Information Layer” as model template. Of course you can also create the single packages and diagrams manually, but for the beginning the template is useful to get an idea about the concept.

This step creates a new package named “SGAM Information Layer” within your model. The content of this package is an appropriate sub package for each of the three necessary steps.

8.2.1. Develop Business Context View

The Business Context View models the information object flows between individual components. It can be developed following the steps below:

1. Open the “Business Context View” Diagram as created from the Model Wizard or create this diagram manually
2. Place all components in the diagram. Hint: If you copy the elements from the Component Layer, you will have arranged them in the same way as in the Component Layer

3. *Hide Relations.* After placing the components in the diagram, all relations (e.g. ICT Associations, Electric Associations) as introduced so far will be visible. As we are not interested in these relations within the Information Layer, you can make them invisible. Open the “Diagram” Drop-Down Menu, select “Advanced” → “Visible Relations” and deselect all relations. Do not accidentally delete these relations instead of making them invisible. Deleting them will delete them not only from the diagram but from the model, so you won’t see them in the original diagrams anymore.
4. *Create Information Object Flows.* In the Primary Use Case Diagram we identified which Information Objects are to be communicated between logical actors. Use the “Information Object Flow” Relation to model these flows here as well and select the appropriate “Information Objects” in the Pop-up window. *Note: This step is some “copy” task, in a future version of the SGAM Toolbox this will be automated.*

Figure 17 - Business Context View (Example)

8.2.2. Perform Standard and Information Object Mapping

1. *Open the “Standard and Information Object Mapping” Diagram as created from the Model Wizard or create this diagram manually*

2. Place all components in the diagram. Hint: If you copy the elements from the Component Layer, you will have arranged them in the same way as in the Component Layer
3. Turn the visibility of all relations – except the Information Object Flows – off
4. Create appropriate “Data Model Standard” Elements and associate the related components with them by using the “Associates Data Model Standard” relations.
5. Place all used Information Objects in the diagram and state the relations between Data Model Standards and Information Objects by using the “Provides Information Object” relations.

Figure 18 - Standard and Information Object Mapping (Example)

8.2.3. Develop Canonical Data Model View

1. Open the “Canonical Data Model View” Diagram as created from the Model Wizard or create this diagram manually
2. Place all components in the diagram. Hint: If you copy the elements from the Component Layer, you will have arranged them in the same way as in the Component Layer.
3. Place all related “Data Model Standard” Elements in the diagram

4. Resize and arrange the “Data Model Standard” Elements over domains and zones according to their associated components

Figure 19 - Canonical Data Model View (Example)

8.3. Develop Communication Layer

The focus of the Communication Layer is to depict the used technology and protocols for the communication between single components.

You can model this layer by following the steps below.

1. Start the Model Wizard (Menu → Project → New Model) and select “SGAM Toolbox” as Technology and “SGAM Communication Layer” as model template. Of course you can also create the single packages and diagrams manually, but for the beginning the template is useful to get an idea about the concept.
2. Place all components in the diagram. Hint: If you copy the elements from the Component Layer, you will have arranged them in the same way as in the Component Layer.
3. Hide Relations. After placing the components in the diagram, all relations (e.g. ICT Associations, Electric Associations) as introduced so far will be visible. As we are not interested in these relations within the Information Layer, you can make them invisible. Open the “Diagram” Drop-Down Menu, select “Advanced” → “Visible Relations” and deselect all relations. Do not accidentally delete these relations instead of making them invisible. Deleting them will delete them not only from the diagram but from the model, so you won’t see them in the original diagrams anymore.
4. Use the “Communication Path” Relations to model the communication paths between the components
5. For every communication path define the protocol and the technology as tagged value

Figure 20 - SGAM Communication Layer (Example)

9. Design and Development of single Components

The development of all five SGAM layer delivers a big picture of a distributed smart grid system. For every component it is defined, which functionality it has to deliver and how it interacts with its surrounding components over all interoperability layers.

For the development of one, specific component out of this distributed system you could say that the systems' context and the systems' interfaces are defined. The system (component) itself is yet treated as black box. During the development of this system, the black box now is to be turned into a white box.

To start the development one component it is a very valuable possibility, to show the functionality and all interfaces over all interoperability layers in one diagram. This can easily achieved by following the steps below:

1. Make the system (component) of interest composite and create a new diagram
2. Place the component in this diagram
3. Right click on the component and select "insert related elements". Now all related elements and the relations are placed into this diagram.

Figure 21 - Component Responsibility Model (Example)

10. Generating Reports

The generation of reports is a very powerful possibility delivered by Enterprise Architect. You can both, create HTML reports (Click through the whole model in an ordinary Internet Browser) or create documents.

The toolbox provides some useful templates which directly can be used for the generation of reports or which can be extended according to the individual needs. These templates are available in the "Resources" View under the section "Templates → Document Templates → SGAM Toolbox".

As the possibilities for automated generation of reports are vast and hence, introduce a certain complexity, the publication of a video tutorial according this task is scheduled in near future.

11. Acknowledges and Future Work

The financial support of the Josef Ressel Center by the Austrian Federal Ministry of Economy, Family and Youth and the Austrian National Foundation for Research, Technology and Development is gratefully acknowledged.

Funding by the Austrian Federal Ministry for Transport, Innovation and Technology and the Austrian Research Promotion Agency (FFG) under Project 838793, "INTEGRA", is gratefully acknowledged.

As the SGAM Toolbox appears to be a very useful help for architecting Smart Grid Systems continuous development is planned. The features for the next iteration will be selected according to the gained experience during application in various projects. However, a few feature requests already exist as you can find below:

- Integration/Import of the Intelligrid Use Case Template
- Visualization
- Integration of Libraries
 - ENTSO-E Role Model
 - M/490 Use Case Management Repository
 - M/490 Actor List
 - ICT Component Library
 - Data Model Standards
 - Protocol/Technology Standards
 - ...
- Automate Model Transformations
 - Use Case ↔ Component Mapping
 - Information Object Flows
- Logic Mapping of Elements to Domains/Zones
- Element Attribute Refinements
